

EXP 2: Run a basic Word Count Map Reduce program to understand Map Reduce Paradigm.

AIM:

To run a basic Word Count MapReduce program.

Procedure:

Step 1: Create Data File:

Create a file named "word_count_data.txt" and populate it with text data that you wish to analyse.

Login with your hadoop user.

```
nano word_count.txt
```

Output: Type the below content in word_count.txt

```
GNU nano 7.2 word_count.txt
Made it to LA yeah
Finally in LA yeah
Lookin for the weed though
Tryna make my own dough
Callin for Maria
Lost without Maria
Might dive in the marina

[ Read 7 lines ]
^G Help      ^O Write Out  ^W Where Is   ^K Cut        ^T Execute    ^C Location
^X Exit      ^R Read File  ^_ Replace    ^U Paste      ^J Justify    ^_ Go To Line
```

Step 2: Mapper Logic - mapper.py:

Create a file named "mapper.py" to implement the logic for the mapper. The mapper will read input data from STDIN, split lines into words, and output each word with its count.

```
nano mapper.py
# Copy and paste the mapper.py code

#!/usr/bin/env python3
# import sys because we need to read and write data to STDIN and STDOUT
#!/usr/bin/python3
import sys
for line in sys.stdin:
    line = line.strip() # remove leading and trailing whitespace
    words = line.split() # split the line into words
    for word in words:
```

```
print( '%s\t%s' % (word, 1))
```

Step 3: Reducer Logic - reducer.py:

Create a file named "reducer.py" to implement the logic for the reducer. The reducer will aggregate the occurrences of each word and generate the final output.

```
nano reducer.py
# Copy and paste the reducer.py code
```

reducer.py

```
#!/usr/bin/python3
from operator import itemgetter
import sys
current_word = None
current_count = 0
word = None
for line in sys.stdin:
    line = line.strip()
    word, count = line.split('\t', 1)
    try:
        count = int(count)
    except ValueError:
        continue
    if current_word == word:
        current_count += count
    else:
        if current_word:
            print( '%s\t%s' % (current_word, current_count))
            current_count = count
            current_word = word
        if current_word == word:
            print( '%s\t%s' % (current_word, current_count))
```

Step 4: Prepare Hadoop Environment:

Start the Hadoop daemons and create a directory in HDFS to store your data.

```
start-all.sh
hdfsdfs -mkdir /word_count_in_python
hdfsdfs -copyFromLocal /path/to/word_count.txt/word_count_in_python
```

Step 6: Make Python Files Executable:

Give executable permissions to your mapper.py and reducer.py files.

```
chmod 777 mapper.py reducer.py
```

Step 7: Run Word Count using Hadoop Streaming:

Download the latest hadoop-streaming jar file and place it in a location you can easily access.

Then run the Word Count program using Hadoop Streaming.

```
hadoop jar /path/to/hadoop-streaming-3.3.6.jar \
-input /word_count_in_python/word_count_data.txt \
-output /word_count_in_python/new_output \
-mapper /path/to/mapper.py \
-reducer /path/to/reducer.py
```

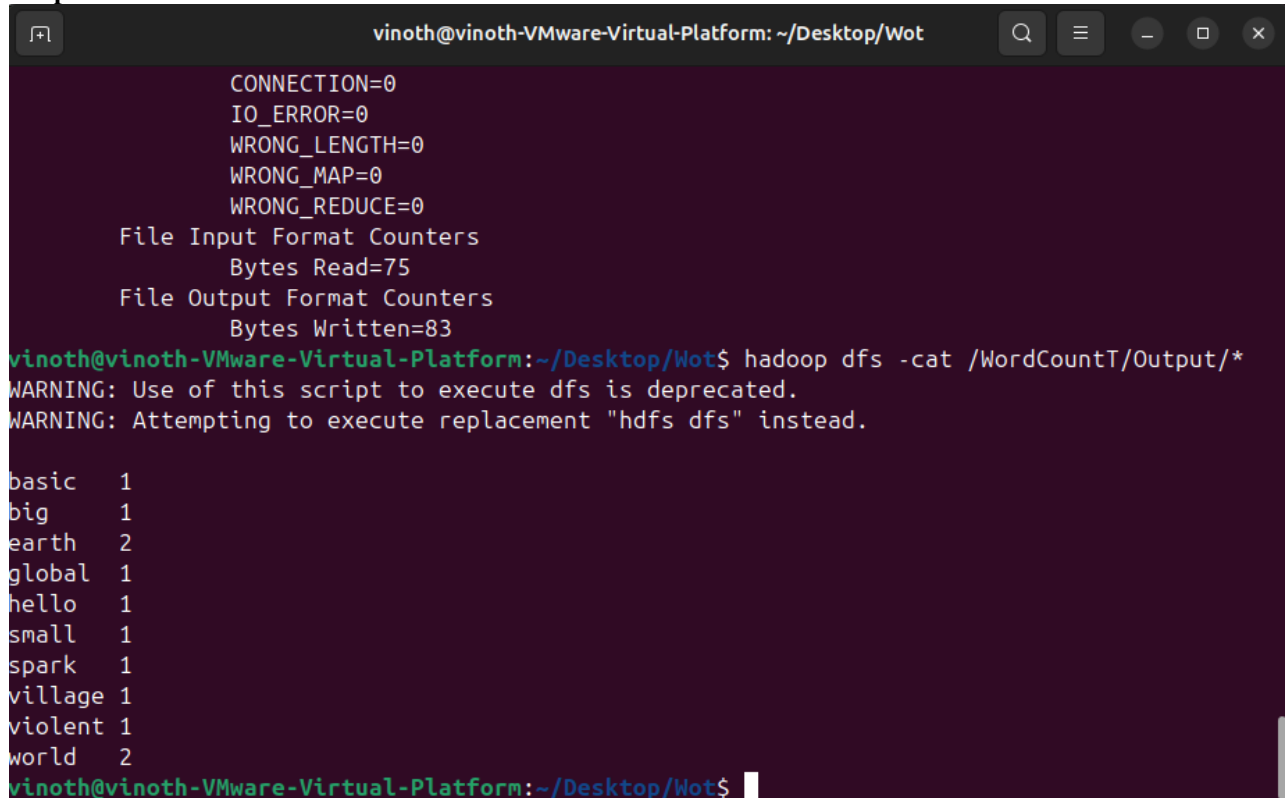

```
hadoop@sanjay-VirtualBox:~/wordcount$ hadoop jar /home/hadoop/Documents/hadoop-streaming-3.3.6.jar -input
t /word_count_in_python/word_count.txt -output /word_count_in_python/output -mapper mapper.py -r
educer reducer.py

violent 1
world 2
vinoth@vinoth-VMware-Virtual-Platform:~/Desktop/Wot$
```

The screenshot shows a text editor window with a title bar that includes the file name 'input.txt' and the path '~/Desktop/Wot/input_data'. The window has standard macOS-style window controls (red, yellow, green buttons) and a menu bar with 'Open' and a file icon. Below the title bar, there is a tab labeled 'input.txt' and a button labeled 'New Document'. The main text area contains the following text:

```
hello world  
big world  
small earth  
global village  
basic spark  
violent earth
```

Result:

Thus, the program for basic Word Count Map Reduce has been executed successfully.
